

4. Write a PHP function

a) To print your name.

b) To print the size of a string. Pass string as an argument

c) To accept variable length arguments and display sum of all values and total number of arguments.

Explanation

a) printName()

A simple function with no parameters.

b) stringSize()

Uses `strlen()` to get length of the given string.

c) sumOfValues(...\$numbers)

Uses **spread operator (...)** to accept unlimited arguments.

Then:

- `array_sum()` → adds all values
- `count()` → counts how many arguments were passed

PHP Program with All Required Functions

```
<?php
```

```
// a) Function to print your name
```

```
function printName() {  
    echo "My Name is Payal Vasoya<br>";  
}
```

```
// b) Function to print size of a string (string as argument)
```

```
function stringSize($str) {  
    echo "String: $str<br>";  
    echo "Size of string: " . strlen($str) . "<br><br>";  
}
```

```
// c) Function to accept variable length arguments and display sum & total
count
function sumOfValues(...$numbers) {
    $sum = array_sum($numbers);
    $count = count($numbers);

    echo "Numbers: ";
    print_r($numbers);
    echo "<br>";

    echo "Total Number of Arguments: $count<br>";
    echo "Sum of All Values: $sum<br><br>";
}

// -----
// Calling the functions
// -----

printName(); // a)
stringSize("Hello PHP Programming"); // b)
sumOfValues(10, 20, 30, 40, 50); // c)

?>
```
